

Procurement Agent PRD

Problem Statement

Company administrators waste time placing multiple orders across different suppliers to meet specific goals. They need to manually search for best prices, compare products, and coordinate orders — a process that lacks both time and support, especially for complex, multi-item purchases aimed at cost reduction.

Evidence of User Value

Users always complain about the lack of time and support when it comes to specific multi tasks and goals.

Target Segments

Primary: Administrators in companies registered in the app who need to place orders for the company.

JTBD: Lower company expenses while maintaining product quality through efficient multi-supplier procurement.

Use Cases

1. As an administrator, when I need to host a dinner for 50 persons, the agent helps me find the best menu options across suppliers based on current prices.
2. As a company buyer, when I need to fulfill a complex order with multiple product categories, the agent helps me combine items from different suppliers into one optimized proposal.
3. As an administrator under budget pressure, when I need to lower costs, the agent helps me identify and order the most cost-effective products that meet my requirements.
4. As a busy procurement lead, when I need to place orders quickly, the agent helps me save time by researching, proposing, and executing orders across multiple suppliers.

Proposed Solution

The agent acts as a **collaborative purchase researcher** that autonomously scans relevant suppliers to find the best prices and products for the user's stated goal, creates a proposal for approval, then places orders across multiple suppliers.

Autonomy level justification: Agent (not Copilot) because users lack time for manual research and need autonomous execution after approval. The agent owns the full research-to-order workflow while maintaining human control at the approval checkpoint.

Agent Design

Goal: Deliver a suggestion of a complex order and after approval place order

Input: User requests a goal, for example "i need to host an dinner for 50 persons, what is the best menu according to prices right know"

Trigger: A company needs to lower their costs and finds our service

Tasks: A collaborative purchase researcher thats scans the relevant suppliers to find the best prices and products for the goal. Create a proposal for the human to approve and then go and place the orders to the suppliers.

Output: Fetches best products and prices from different suppliers in the portal and present the options; Order placed to the suppliers and saving confirmed

Tools: Suppliers pages, Supplier policies, Supplier agreements, Dashboard

Human-AI Interaction Flow

1. **Human does:** Triggers the goal (writes in conversation window in side panel with agent, can upload content and material) → **Agent does:** [To validate: specific agent response] → **Human sees:** The conversation window and agent acknowledgment
2. **Human does:** [Waits] → **Agent does:** Scans relevant suppliers, fetches best products and prices from different suppliers in the portal → **Human sees:** See the agent thinking and working
3. **Human does:** Reviews and approves → **Agent does:** Presents options → **Human sees:** The proposal of products and prices
4. **Human does:** [Approves] → **Agent does:** Places order to the suppliers → **Human sees:** The order confirmation
5. **Human does:** Gets notified about order status → **Agent does:** Confirms saving → **Human sees:** The total savings in the chat

HITL Guardrails

Review Point 1 — Proposal Approval

- **Trigger:** Agent completes product/price proposal
- **What human sees:** The proposal of products and prices
- **Action required:** Review and approve
- **Default if skipped:** [Open — define timeout behavior]

Review Point 2 — Order Confirmation [Open — validate if this is informational or requires action]

- **Trigger:** Order placed
- **What human sees:** The order confirmation, total savings
- **Action required:** [To validate]

- **Default if skipped:** [To validate]

Goals & Success Metrics

1. **Proposal relevance:** The proposal of products achieves the user goal (relevance score: [To validate method])
2. **Order success rate:** The placement of the order is successful after user approval
3. **Time saved:** [To validate — baseline manual ordering time vs. agent-assisted time]
4. **Cost savings realized:** [To validate — track actual savings vs. projected]
5. **Approval rate:** [To validate — % of proposals approved without iteration]

Dependencies, Risks & Open Questions

Dependencies:

- Access to supplier pages, policies, and agreements
- Dashboard integration for savings tracking [Open — technical scope]

Risks:

- Proposal quality depends on supplier data accuracy [Open — data quality validation process]
- Order placement failures across multiple suppliers [Open — error handling and rollback strategy]
- User approval delays blocking order timing/pricing [Open — proposal expiration policy]

Open Questions:

1. What happens if user doesn't approve within X timeframe? Price validity?
2. How does agent handle out-of-stock items after approval?
3. What level of customization can users request during review?
4. How are supplier policies/constraints factored into proposals?
5. What user evidence exists beyond "lack of time and support" complaint? Interviews? Support tickets? Behavioral data?
